## 数据结构

[TOC]

### 1. 离散化

```
数组版
   for(int i = 1; i <= n; i++) std::cin >> a[i], b[i] = a[i];
   std::sort(a + 1, a + 1 + n);
   len = std::unique(a + 1, a + 1 + n) - a - 1;
   auto query_pos = [\&](int x) { return std::lower_bound(a + 1, a + 1 + len, x) - a; };
   向量版
   vector<int> a;
   std::sort(a.begin(),a.end());
   a.erase(unique(a.begin(),a.end()),a.end());
   auto query_pos = [&](int x) { return lower_bound(a.begin(), a.end(), c) - a.begin() + 1;
   //查找下标从 1 开始
   }
   2. 并查集
   路径压缩+按秩合并
   struct UnionFind {
1
       std::vector<int> par, rank, size;
       int c:
3
       UnionFind(int n): par(n), rank(n, 0), size(n, 1), c(n) {
           for(int i = 0; i < n; ++i) par[i] = i;
5
       int find(int i) { return (par[i] == i ? i : (par[i] = find(par[i]))); }
       bool same(int i, int j) { return find(i) == find(j); }
       int get_size(int i) { return size[find(i)]; }
       int count() { return c; }
10
       int merge(int i, int j) {
11
          if((i = find(i)) == (j = find(j))) return -1;
12
           else --c;
13
           if(rank[i] > rank[j]) std::swap(i, j);
           par[i] = j, size[j] += size[i];
15
           if(rank[i] == rank[j]) rank[j]++;
16
           return j;
17
18
   };
   可回滚并查集
       注意这个不是可持久化并查集
       ● 查找时不进行路径压缩
       • 复杂度靠按秩合并解决
   namespace uf {
```

```
1
        int fa[maxn], sz[maxn];
        int undo[maxn], top;
        void init() { memset(fa, -1, sizeof fa); memset(sz, 0, sizeof sz); top = 0; }
        int findset(int x) { while (fa[x] != -1) x = fa[x]; return x; }
        bool join(int x, int y) {
           x = findset(x); y = findset(y);
            if (x == y) return false;
            if (sz[x] > sz[y]) swap(x, y);
            undo[top++] = x;
            fa[x] = y;
11
12
            sz[y] += sz[x] + 1;
            return true;
13
14
        inline int checkpoint() { return top; }
15
        void rewind(int t) {
16
            while (top > t) {
```

```
int x = undo[--top];
18
19
                sz[fa[x]] = sz[x] + 1;
20
                fa[x] = -1;
21
22
        }
   }
23
    3.ST 表

    预处理: O(n log n)

       查询: O(1)
   #include <bits/stdc++.h>

    4. 树状数组 (Fenwick)
    朴素树状数组
    查询区间第 K 大需要权值树状数组!
    namespace Fenwick{
        int tree[N], len;
        #define lowbit(x) ((x) & (-x))
3
        inline void init(){
           memset(tree, 0, sizeof(tree));
            for(int i = 1, tmp = 0; i <= len; i++){
               tree[i] += a[i];
                tmp = i + lowbit(i);
```

```
if(tmp <= len) tree[tmp] += tree[i];</pre>
9
10
11
12
        inline void update(int i, int x){
            for(int pos = i; pos <= len; pos += lowbit(pos)) tree[pos] += x;</pre>
14
15
16
        inline int getsum(int i, int ans = 0){
17
18
            for(int pos = i; pos; pos -= lowbit(pos)) ans += tree[pos];
            return ans:
19
20
21
        inline int query(int l, int r){ return getsum(r) - getsum(l - 1); }
22
23
        //* 查询区间第 K 大需要权值树状数组!
24
25
        int kth(int i){
            int cnt = 0, ret = 0;
26
             for(int i = log2(len); ~i; --i){
28
                ret += 1 << i;
                 (ret >= len || cnt + tree[ret] >= i) ? (ret -= 1 << i) : (cnt += tree[ret]);</pre>
29
            return ret + 1;
31
    }
```

#### 区间加/区间求和

若维护序列 a 的差分数组 b,此时我们对 a 的一个前缀 r 求和,即  $\sum_{i=1}^r a_i$ ,由差分数组定义得  $a_i = \sum_{j=1}^i b_j$  进行推导

$$\begin{split} &\sum_{i=1}^r a_i \\ &= \sum_{i=1}^r \sum_{j=1}^i b_j \\ &= \sum_{i=1}^r b_i \times (r-i+1) \\ &= \sum_{i=1}^r b_i \times (r+1) - \sum_{i=1}^r b_i \times i \end{split}$$

区间和可以用两个前缀和相减得到,因此只需要用两个树状数组分别维护  $\sum b_i$  和  $\sum i \times b_i$ ,就能实现区间求和。

```
namespace Fenwick_Plus{
       #define lowbit(x) ((x) & (-x))
2
        #define MAXN $Array_Max_Sizes$
        int tree1[MAXN], tree2[MAXN], a[MAXN], len;
        //对两个树状数组进行更新
        inline void add(int i, int x){
            int x1 = i * x;
            for(int pos = i; pos <= len; pos += lowbit(pos)) tree1[pos] += x, tree2[pos] += x1;</pre>
        //将区间加差分为两个前缀和
11
       inline void update(int l, int r, int x){
           add(l, x), add(r + 1, -x);
12
13
       //对指定的树状数组求前 n 项和
14
       inline int getsum(int *tree, int i){
            int sum = 0;
16
17
            for(int pos = i; pos; pos -= lowbit(pos)) sum += tree[i];
18
            return sum;
19
        //区间和查询
       inline int query(int l, int r){
21
            return (r + 1) * getsum(tree1, r) - l * getsum(tree1, l - 1) - (getsum(tree2, r) - getsum(tree2, l - 1));
22
23
```

24 }

## 5. 线段树模板

### (1). 朴素线段树

区间和:区间修改/单点修改/单点查询/区间查询

```
#define SEGRG 1, 1, n //! 此处定义范围, 注意 n 取值
    const int N = 1e5 + 10;
3

            if(mid < R) ans += query(rson[rt], mid + 1, r, L, R);
            return ans:
49
   }//DynamicSegmentTree
```

## 6. 可持久化权值线段树 (主席树)

## 0. 模板题/模板封装

给定排列  $p_1,p_2,p_3,\ldots,p_n$ ,定义  $A_i$  表示在  $p_i$  左侧并比  $p_i$  小的数字个数,  $B_i$  表示在  $p_i$  右侧并比  $p_i$  小的数字个数,  $C_i=\min(A_i,B_i)$ 。 现在给定多个操作 (l,r),求每个操作,交换  $(p_i,p_j)$  后的  $\sum C_i$ 。

首先考虑如何处理初始时的 $C_i$ 值,观察到以下性质:

- 对于  $A_i$  值的求解过程类似求逆序对的思想,可以直接上树状数组维护, $O(n \log n)$  求得全部的  $A_i$
- 由于是排列, $B_i = p_i 1 A_i$  可以 O(1) 求得
- 那么  $C_i = \min(A_i, B_i)$  也是 O(1) 得到的

由于每个询问相互独立,那么考虑交换  $(p_l, p_r)$  操作对  $C_i$  的影响:

- 对于 [1,l),(r,n] 范围的数字, $C_i$  值一定不影响。因为交换操作均在单侧进行
- 对于  $p_l$ ,交换到 r 位置后, $A_l \to A_l + [l,r] p_l$  ,  $B_l$ '仍然可以直接求对于  $p_r$ ,交换到 l 位置后, $A_r \to A_r [l,r] p_r$  ,  $B_r$ '仍然可以直接求如果我们在线询问 (主席树维护),那么对于  $p_l$ , $p_r$ ,实际上可以直接两个 O(logn) 重新求。
- 那么重点是对于 [l+1,r-1] 区间内的数字的  $C_i$  值变化,如何维护?
- 对于  $p_l \leq p_i \leq p_r$ ,如果  $A_i \leq B_i$ ,则交换后  $A_i 1, B_i + 1$ ,从而  $C_i 1$  对于  $p_l \geq p_i \geq p_r$ ,如果  $A_i \geq B_i$ ,则交换后  $A_i + 1, B_i 1$ ,从而  $C_i 1$
- 对于  $p_l \leq p_i \leq p_r$ ,如果  $A_i-1 \geq B_i+1, A_i \geq B_i$ ,则交换后  $C_i+1$  对于  $p_l \geq p_i \geq p_r$ ,如果  $A_i-1 \leq B_i+1, A_i \leq B_i$ ,则交换后  $C_i+1$

那么对于以上四种情况,我们可以分别用四棵主席树进行维护。同时,对于  $p_l,p_r$  的贡献计算还需要支持区间 < K 的数字个数查询,因此共需五棵主席树进行维护,复杂度  $O(m \times 4\log n)$ 。

```
namespace PresidentTree{
       int root[N], sum[N << 5][5], lc[N << 5], rc[N << 5], cnt;</pre>
        #define ls l, mid

37
38
39
         return 0:
40
```

### 2. 主席树维护线段树区间修改 (标记永久化)

主席树可以维护线段树的区间修改、但是要求线段树动态开点。

在区间更新的时候,对每个点打永久化标记,对于跨越区间的点需要直接修改。查询时找到对应的完全覆盖区间加上这个区间的标记\*(区间长度)

```
#include <bits/stdc++.h>
1
    #define ll long long
    using namespace std;
    const int N = 1e5 + 10;
    int root[N], lc[N << 6], rc[N << 6], tot = 0, cur = 0;</pre>
    ll sum[N << 6], lazy[N << 6];</pre>
    int n, m;
    void build(int &rt, int l, int r){
10
        rt = ++tot, lazy[rt] = 0;
11
12
        if(1 == r){}
            scanf("%lld", &sum[rt]);
13
14
             return;
        7
15
16
        int mid = l + r >> 1;
        build(lc[rt], l, mid);
17
        build(rc[rt], mid + 1, r);
18
19
        sum[rt] = sum[lc[rt]] + sum[rc[rt]];
    }
20
21
    void update(int &rt, int pre, int l, int r, int L, int R, int c){
22
        rt = ++tot, lc[rt] = lc[pre], rc[rt] = rc[pre], lazy[rt] = lazy[pre], sum[rt] = sum[pre] + 1ll * (min(r, R) - max(l, r))
23
     if(L >= 1 \&\& R <= r){}
24
25
            lazy[rt] += c;
26
            return:
27
28
        int mid = L + R >> 1;
29
        if(l <= mid) update(lc[rt], lc[pre], l, r, L, mid, c);</pre>
30
        if(r > mid) update(rc[rt], rc[pre], l, r, mid + 1, R, c);
31
32
    Il query(int rt, int L, int R, int l, int r){
33
34
        if(L >= l && R <= r) return sum[rt];</pre>
        int mid = L + R >> 1;
35
        ll ans = lazy[rt] * (min(r, R) - max(l, L) + 1);
36
37
        if(l <= mid) ans += query(lc[rt], L, mid, l, r);</pre>
        if(r > mid) ans += query(rc[rt], mid + 1, R, l, r);
38
        return ans;
39
    }
40
41
    signed main(){
42
        while(scanf("%d%d", &n, &m) != EOF){
43
             char op[10];
44
             cur = tot = 0:
45
            build(root[0], 1, n);
```

```
while(m--){
47
48
                 scanf("%s", op);
                 if(op[0] == 'C'){
49
50
                     int l, r, c;
51
                     scanf("%d%d%d", &l, &r, &c);
                     cur++:
52
                     update(root[cur], root[cur - 1], l, r, 1, n, c);
53
54
                 else if(op[0] == 'Q'){
55
                     int l, r;
                     scanf("%d%d", &l, &r);
57
58
                     printf("%lld\n", query(root[cur], 1, n, l, r));
59
                 else if(op[0] == 'H'){
60
61
                     int l, r, h;
                     scanf("%d%d%d", &l, &r, &h);
62
63
                     printf("%lld\n", query(root[h], 1, n, l, r));
64
                 else if(op[0] == 'B'){
                     scanf("%d", &cur);
66
67
                 }
            }
68
        7
69
        return 0;
```

#### 3. 求区间内不同的数字个数/求区间大于 K 的数字有多少

求区间内不同数字个数的问题可以转化为求区间内小于等于 K 的数字个数:

对于每个数字记录下一个最近的相同数字下标 nxt[i],那么查询区间 [L,R] 内不同数字的个数实际上就是在查询区间内 nxt[i] > R 的个数 (下一个相同的数字位于区间之外)。那么现在不难发现对于给定区间 [l,r],如果 nxt[i] > r, $i \in [l,r]$ ,那么表示与 i 相同数字点位于区间之外。那么求不同数字个数问题便转化为给定求所有满足 l <= i <= r,nxt[i] > r 的个数。

那么我们只需要处理出nxt数组,然后用主席树对每个节点维护权值数组,然后区间查询数目即可。

```
#include <bits/stdc++.h>
    using namespace std:
2
    const int N = 1e6 + 10:
    int a[N], head[N], nxt[N];
    int root[N], sum[N << 5], lc[N << 5], rc[N << 5], cnt;</pre>
    inline int read(){
        int f = 1, x = 0; char s = getchar();
        while(s < 0'||s > 9'){ if(s =='-') f = -1; s = getchar(); }
10
        while(s >= '0' && s <= '9'){ x = x * 10 + s - '0'; s = getchar();}
11
        return x *= f;
12
13
14
    void build(int &rt, int l, int r){
15
16
        rt = ++cnt:
        if(l == r) return;
17
18
        int mid = l + r >> 1;
        build(lc[rt], l, mid);
19
20
        build(rc[rt], mid + 1, r);
    }
21
22
23
    void update(int &rt, int pre, int l, int r, int x){
        rt = ++cnt, lc[rt] = lc[pre], rc[rt] = rc[pre], sum[rt] = sum[pre] + 1;
24
        if(l == r) return;
25
        int mid = l + r >> 1;
26
        if(x <= mid) update(lc[rt], lc[pre], l, mid, x);</pre>
28
        else update(rc[rt], rc[pre], mid + 1, r, x);
    }
29
30
    int query(int L, int R, int l, int r, int k){
31
        if(l == r) return sum[R] - sum[L];
32
        int mid = l + r >> 1, ans = 0;
33
        if(k \le mid) ans += query(lc[L], lc[R], l, mid, k) + sum[rc[R]] - sum[rc[L]];
34
35
        else ans += query(rc[L], rc[R], mid + 1, r, k);
```

```
return ans:
36
37
    }
38
    signed main(){
39
40
        int n = 0;
        n = read();
41
        for(int i = 1; i <= n; i++){
42
            a[i] = read(); //cin >> a[i];
43
            if(head[a[i]]) nxt[head[a[i]]] = i;
44
45
            head[a[i]] = i;
46
47
        for(int i = 1; i <= n; i++)
48
            if(!nxt[i]) nxt[i] = n + 1;
49
50
        build(root[0], 1, n + 1);
        for(int i = 1; i <= n; i++) update(root[i], root[i - 1], 1, n + 1, nxt[i]);</pre>
51
52
        int m = read();
53
54
        while(m--){
            int l = read(), r = read();
55
            printf("%d\n", query(root[l-1], root[r], 1, n + 1, r + 1));
56
57
        return 0:
58
```

### 4. 求区间小于等于 K 的数字个数 (二分查询)

建立权值数组,对每个节点维护一颗主席树。查询为单点查询,查询数字对应的权值数组的个数。然后对于每个询问,我们在区间内二分枚举所有可能的数字 k , 然后查询区间第 k 小。反复查询求得一个满足 k < k 的最大 k 。那么这个 k 就是我们想要得到的答案。

```
#include <bits/stdc++.h>
    #define ll long long
    using namespace std;
    const int N = 1e5 + 10:
    ll root[N], sum[N << 5], lc[N << 5], rc[N << 5], tot = 0;</pre>
    ll a[N], b[N];
    inline void update(ll &rt, ll pre, ll l, ll r, ll k){
10
11
        rt = ++tot, lc[rt] = lc[pre], rc[rt] = rc[pre], sum[rt] = sum[pre] + 1;
        ll\ mid = l + r >> 1;
12
        if(l == r) return;
13
14
        if(k <= mid) update(lc[rt], lc[pre], l, mid, k);</pre>
        else update(rc[rt], rc[pre], mid + 1, r, k);
15
17
    ll query(ll u, ll v, ll L, ll R, ll k){
18
19
        if(L == R) return L;
        ll mid = L + R >> 1;
20
21
        ll res = sum[lc[v]] - sum[lc[u]];
        if(res >= k) return query(lc[u], lc[v], L, mid, k);
22
        else return query(rc[u], rc[v], mid + 1, R, k - res);
23
    }
24
25
26
    signed main(){
        ios_base::sync_with_stdio(false), cin.tie(0), cout.tie(0);
27
        int t = 0, T = 0; cin >> t;
28
        while(t--){
29
30
             ll n, m; cin >> n >> m;
31
             for(int i = 1; i <= n; i++){
                 cin >> a[i]; b[i] = a[i];
32
            sort(b + 1, b + 1 + n);
34
             ll sz = unique(b + 1, b + 1 + n) - b - 1;
35
             for(int i = 1; i <= n; i++){
36
                 ll \ x = lower\_bound(b + 1, b + 1 + sz, a[i]) - b;
37
38
                 update(root[i], root[i - 1], 1, sz, x);
39
            cout << "Case " << ++T << ":" << endl;</pre>
            while (m--) {
41
```

```
ll u, v, k; cin >> u >> v >> k;
42
43
                 u++, v++;
                 ll ans = 0, L = 0, R = v - u + 1;
44
45
                 while (L < R) {
                     ll\ mid = (L + R + 1) >> 1;
                      ll t = query(root[u - 1], root[v], 1, sz, mid);
47
                      if(b[t] \le k) L = mid;
48
                     else R = mid - 1;
49
50
51
                 cout << L << endl;</pre>
            }
52
53
        }
54
        return 0;
55
```

#### 5. 求区间 Mex

给定 n 长度的数组, $\{a_1,a_2,...,a_n\}$ ,以及 m 次询问,每次给出一个数对 (l,r) 表示区间起点终点,要求对于给定的询问,回答在该区间内最小未出现的数字。

建立权值数组,对于每个点建立一棵主席树,维护权值最后一次出现的位置,那么对于查询 [l,r] 就是查找第 r 棵树上出现位置小于 l 的权值,那么只需要维护最后一次出现位置的最小值即可。

主席树解决该问题属于在线算法。这种题目可以用莫队强制离线处理。

```
#include <bits/stdc++.h>
    using namespace std;
    const int N = 2e5 + 10;
    int tot, root[N], tree[N << 5], lc[N << 5], rc[N << 5];</pre>
    void update(int &rt, int pre, int l, int r, int x, int val){
        rt = ++tot, lc[rt] = lc[pre], rc[rt] = rc[pre];
10
        if(1 == r){
            tree[rt] = val;
11
12
            return;
13
14
        int mid = l + r >> 1;
        if(x <= mid) update(lc[rt], lc[pre], l, mid, x, val);</pre>
15
        else update(rc[rt], rc[pre], mid + 1, r, x, val);
16
17
        tree[rt] = min(tree[lc[rt]], tree[rc[rt]]);
    }
18
19
    int query(int rt, int ql, int l, int r){
20
        if(l == r) return l;
21
22
        int mid = l + r >> 1;
        if(tree[lc[rt]] < ql) return query(lc[rt], ql, l, mid);</pre>
23
        else return query(rc[rt], ql, mid + 1, r);
24
    }
25
26
27
    signed main(){
28
29
        ios_base::sync_with_stdio(false), cin.tie(0), cout.tie(0);
        int n, m; cin >> n >> m;
30
31
        for(int i = 1, x; i \le n; i++){
            cin >> x; x++;
32
             if(x > n) root[i] = root[i - 1];
33
34
            else update(root[i], root[i - 1], 1, n + 1, x, i);
35
        while(m--){
36
            int l, r; cin >> l >> r;
37
            cout << query(root[r], l, 1, n + 1) - 1 << endl;</pre>
39
        return 0;
40
41
    }
```

## 6. 求区间内出现次数大于 >=k 次的最前数

对于给定的序列,输出待查询区间内出现次数严格大于区间长度一半的数字。

思路:考虑对查询过程进行剪枝,排除非法子树,向合法子树搜索。

首先考虑非法状态:因为对于主席树上任意一个节点,其代表的意义是管辖区间内数字的个数。因此对于主席树上某个节点,如果其代表区间数字的数目比区间长度的一半 (也就是  $\frac{r-l+1}{2}$ )要小,那么子区间不回再出现满足该条件的数,在这种情况下可以直接返回 0。

剩下的部分就是查询的板子。非法状态实际上就是在对查询过程进行剪枝。

```
#include <bits/stdc++.h>
    using namespace std;
    const int N = 5e5 + 10;
    int a[N], b[N];
    int tot, root[N << 5], sum[N << 5], lc[N << 5], rc[N << 5];</pre>
    void update(int &rt, int pre, int l, int r, int v){
        rt = ++tot, lc[rt] = lc[pre], rc[rt] = rc[pre], sum[rt] = sum[pre] + 1;
10
        if(l == r) return;
11
        int mid = l + r >> 1;
12
        if(v <= mid) update(lc[rt], lc[pre], l, mid, v);</pre>
13
14
        else update(rc[rt], rc[pre], mid + 1, r, v);
15
   }
16
    int query(int L, int R, int l, int r, int k){
17
        if(sum[R] - sum[L] <= k) return 0;</pre>
18
        if(l == r) return l;
19
        int now = sum[lc[R]] - sum[lc[L]], mid = l + r >> 1;
20
21
        if(now > k) return query(lc[L], lc[R], l, mid, k);
22
        else return query(rc[L], rc[R], mid + 1, r, k);
   }
23
24
25
    signed main(){
26
        ios_base::sync_with_stdio(false), cin.tie(0), cout.tie(0);
27
        int n, q; cin >> n >> q;
        for(int i = 1; i <= n; i++){
28
            cin >> a[i];

## 7. 主席树 + 树上路径

给定一棵n个节点的树,每个点有一个权值。有m个询问,每次给你u,v,k你需要回答uxor last 和v这两个节点间第k小的点权。 动态查询树上区间点权第k小,且查询之间具有关系,因此考虑建立主席树维护区间信息。

首先回顾主席树维护线性区间第 k 大/小时我们的处理思路:

对于全局区间第 k 小时,我们建立全局权值线段树,维护的区间和表示某点子树中点的个数。那么我们在寻找区间第 k 小时,只需要左右二分寻找即可。而对于某个区间的第 k 小,一个朴素的方式便是我们每次都建立一颗线段树,但显然这样是不明智的算法。那么我们是如何查询这个区间第 k 小的呢?

对于这个维护的过程我们很容易联想到前缀和的概念,我们可以先离线建树,对于每个点建立一棵主席树,维护 [1,i] 区间,那么对于区间查询 [l,r] 时,我们只需要查询到区间 [1,l-1] 和 [1,r] 即可取得区间的信息,实现区间查询。

然后分析样例, 作出样例所示的树 (假设以1为根节点):

那么我们可以发现,对于树上区间查询,我们也可以利用类似于线性区间查询的思路进行解决,但是由于树的结构限制,我们把线性区间

的前缀和改为树上前缀和的形式: query(u, v) = sum[u] + sum[v] - sum[lca(u, v)] - sum[fa[lca(u, v)]] 下面我们来说明这个式子:

如上,从根节点到 5 号节点的路径 + 从根节点到 7 号节点的路径重复了两次,那么我们要减去重叠的信息: 对于根节点到交点父节点的信息均重复两次,到交点的信息重复一次 (因为交点在链上,需要保留一次信息),因此前缀和形式便是 sum[u] + sum[v] - sum[lca(u,v)] - sum[fa[lca(u,v)]]。

```
#include <bits/stdc++.h>
    #define id(x) (lower_bound(b + 1, b + le + 1, a[x]) - b)

```

#### 8.K-D Tree

在一个初始值全为0的 $n \times n$ 的二维矩阵上,进行q次操作,每次操作为以下两种之一:

- 1. **1 x y A**: 将坐标 (x,y) 上的数加上 A。
- 2. **2 x1 y1 x2 y2**: 输出以  $(x_1, y_1)$  为左下角,  $(x_2, y_2)$  为右上角的矩形内(包括矩形边界)的数字和。

强制在线。内存限制 20M。保证答案及所有过程量在 int 范围内。

构建 2-D Tree, 支持两种操作:添加一个 2 维点;查询矩形区域内的所有点的权值和。可以使用 带重构的 k-D Tree 实现。

在查询矩形区域内的所有点的权值和时,仍然需要记录子树内每一维度上的坐标的最大值和最小值。如果当前子树对应的矩形与所求矩形没有交点,则不继续搜索其子树;如果当前子树对应的矩形完全包含在所求矩形内,返回当前子树内所有点的权值和;否则,判断当前点是否在所求矩形内,更新答案并递归在左右子树中查找答案。

已经证明,如果在 2-D 树上进行矩阵查询操作,已经被完全覆盖的子树不会继续查询,则单次查询时间复杂度是最优  $O(\log n)$ ,最坏  $O(\sqrt{n})$  的。将结论扩展到 k 维的情况,则最坏时间复杂度是  $O(n^{1-\frac{1}{k}})$  的。

## 10. 笛卡尔树

给定一个  $1 \sim n$  的排列 p,构建其笛卡尔树。

即构建一棵二叉树,满足:

- 1. 每个节点的编号满足二叉搜索树的性质。
- 2. 节点i的权值为 $p_i$ ,每个节点的权值满足小根堆的性质。

这棵树的每个结点有两个子树,分为左右子树,子树可以为空;

- 一个结点的左子树中的所有结点的第一个权值都小于其第一个权值(空子树也满足);
- 一个结点的右子树中的所有结点的第一个权值都大于其第一个权值(空子树也满足);
- 一个结点的两棵子树中的所有结点的第二个权值都大于其第二个权值(空子树也满足)。

```
const int N = 1e7 + 7;
   int n, a[N], stk[N], ls[N], rs[N];
   void build(int n){
       for (int i = 1, pos = 0, top = 0; i <= n; ++i){ //这是按下标顺序插入元素的代码
5
           pos = top;
           while (pos && a[stk[pos]] > a[i]) pos--;
           if (pos) rs[stk[pos]] = i;
           if (pos < top) ls[i] = stk[pos + 1];</pre>
           stk[top = ++pos] = i;
10
11
       }
   }
12
   inline void solve(){
14
       int n = read();
15
       for(int i = 1; i <= n; i++) a[i] = read();
16
      build(n);
17

### 11.Treap

FROM ECNU 板子库

## 原始 Treap

- 非旋 Treap
- v 小根堆
- lower 第一个大于等于的是第几个 (0-based)
- upper 第一个大于的是第几个 (0-based)
- split 左侧分割出 rk 个元素

```
namespace treap {
        const int M = maxn * 17;
2
        extern struct P* const null;
        struct P {
4
             P *ls, *rs;
             int v, sz;
             unsigned rd;
             P(int v): ls(null), rs(null), v(v), sz(1), rd(rnd()) {}
             P(): sz(0) {}
             P* up() { sz = ls - > sz + rs - > sz + 1; return this; }
11
             int lower(int v) {
                  if (this == null) return 0;
13
                  return this->v >= v ? ls->lower(v) : rs->lower(v) + ls->sz + 1;
14
15
             }

## 15. 替罪羊树 (暴力重构二叉搜索树)

很暴力但是很牛逼的结构,平衡系数一般置为 0.75 即可。注意,二叉搜索树本质不变,所有二叉搜索树性质仍然适用。

平衡系数越大插入速度就越快,而访问和删除速度就会降低。反之则插入变慢

```
const int N = 2e5 + 10;
    double alpha = 0.75; //平衡系数
2
    namespace SGT {
4
        struct node {
            int ls, rs;
            int w, wn, s, sz, sd;
        } tree[N];
        int cnt, root;
10
11
        //* recalculate the value of rt
12
13
        void calc(int rt) {
            tree[rt].s = tree[tree[rt].ls].s + tree[tree[rt].rs].s + 1;
14
15
            tree[rt].sz = tree[tree[rt].ls].sz + tree[tree[rt].rs].sz + tree[rt].wn;

```

## 平衡树

- ov\_tree\_tag
- rb\_tree\_tag
- splay\_tree\_tag
- mapped: null\_type 或 null\_mapped\_type (旧版本) 为空
- Node\_Update 为 tree\_order\_statistics\_node\_update 时才可以 find\_by\_order & order\_of\_key
- find\_by\_order 找 order + 1 小的元素 (其实都是从 0 开始计数), 或者有 order 个元素比它小的 key
- order\_of\_key 有多少个比 r\_key 小的元素

• join & split

for (int i = 2; i < M + M; ++i)

```
#include <ext/pb_ds/assoc_container.hpp>
1
   using namespace __gnu_pbds;
  using Tree = tree<int, null_type, less<int>, rb_tree_tag, tree_order_statistics_node_update>;
  Tree t:
   持久化平衡树
   #include <ext/rope>
   using namespace __gnu_cxx;
   rope<int> s;
   int main() {
      FOR (i, 0, 5) s.push_back(i); // 0 1 2 3 4
       s.replace(1, 2, s); // 0 (0 1 2 3 4) 3 4
      auto ss = s.substr(2, 2); // 1 2,
8
      s.erase(2, 2); // 0 1 4
      s.insert(2, s); // equal to s.replace(2, 0, s)
10
11
      assert(s[2] == s.at(2)); // 2
  }
12
   哈希表
   #include<ext/pb_ds/assoc_container.hpp>
   #include<ext/pb_ds/hash_policy.hpp>
   using namespace __gnu_pbds;
   gp_hash_table<int, int> mp;
   cc_hash_table<int, int> mp;
   附录: ZKW 线段树 + 不带修 RMQ(O(N \log \log N) + O(1))
   普通的 zkw 线段树解法分为线性建树和单次 O(logn) 的查询,显然查询是瓶颈。
   观察 zkw 线段树的查询结构:
     for (l += M - 1, r += M + 1; l \land r \land 1; l >>= 1, r >>= 1) {
      if (~l & 1) ret = max(ret, zkw[l ^ 1]);
      if (r & 1) ret = max(ret, zkw[r ^ 1]);
   发现就是两边链查询,查询的信息类似于一条链上所有左/右儿子的兄弟们的最大值。
   它是可以快速合并的,直接采用倍增优化(树上ST表),然后O(1)回答询问。
   由于树高 O(logn), 故预处理 ST 的时空复杂度均为 O(nloglogn)。
   甚至可以原线段树都不要了,直接用数组建出 ST表(见代码)。
   综上, 预处理时间复杂度: O(n \log \log n), 单次查询复杂度 O(1), 空间复杂度 O(n \log \log n), 优点是代码较短。
   例题:第一行输入序列长度和查询数,接着一行输入序列,接着若干行每行一个查询区间,所有输入为10^5以内的正整数。
   #include <bits/stdc++.h>
   using namespace std;
   const int N = 1e5 + 9, Mx = 1 << 17;
  int n, m, M = 1, lg[Mx << 1];</pre>
   pair<int, int> val[Mx << 1][5];</pre>
   int main() {
    scanf("%d%d", &n, &m);
